On Plateaued Functions

Yuliang Zheng Senior Member, IEEE and Xian-Mo Zhang

Abstract—The focus of this paper is on nonlinear characteristics of cryptographic Boolean functions. First, we introduce the notion of plateaued functions that have many cryptographically desirable properties. Second, we establish a sequence of strengthened inequalities on some of the most important nonlinearity criteria, including nonlinearity, avalanche and correlation immunity, and prove that critical cases of the inequalities coincide with characterizations of plateaued functions. We then proceed to prove that plateaued functions include as a proper subset all partially-bent functions that were introduced earlier by Claude Carlet. This solves an interesting problem that arises naturally from previously known results on partially-bent functions. In addition, we construct plateaued, but not partially-bent, functions that have many properties useful in cryptography.

KEY WORDS

Bent Functions, Cryptography, Nonlinear Characteristics, Partially-Bent Functions, Plateaued Functions.

I. MOTIVATIONS

In the design of cryptographic functions, one often faces the problem of fulfilling the requirements of a multiple number of nonlinearity criteria. Some of the requirements contradict others. The most notable example is perhaps bent functions — while these functions achieve the highest possible nonlinearity and satisfy the avalanche criterion with respect to every non-zero vector, they are not balanced, not correlation immune and exist only when the number of variables is even.

Another example that clearly demonstrates how some nonlinear characteristics may impede others is partially-bent functions introduced in [1]. These functions include bent functions as a proper subset. Partially-bent functions are interesting in that they can be balanced and also highly nonlinear. However, except those that are bent, all partially-bent functions have non-zero linear structures, which are considered to be cryptographically undesirable.

The primary aim of this paper is to introduce a new class of functions to facilitate the design of cryptographically good functions. It turns out that some of these cryptographically good functions can maintain all the desirable properties of partially-bent functions while not possessing non-zero linear structures. This new class of functions are called plateaued functions. To study the properties of plateaued functions, we establish a sequence of inequalities concerning nonlinear characteristics. We show that plateaued functions can be characterized by the critical cases of these inequalities. In particular, we demonstrate that plateaued functions reach the upper bound on nonlinearity given by the inequalities.

We also examine relationships between plateaued functions and partially-bent functions. We show that partially-bent functions must be plateaued while the converse is not true. Other useful properties of plateaued functions include that they exist both for even and odd numbers of variables, can be balanced and correlation immune.

The remaining part of the paper is organized as follows. Section II introduces basic concepts on Boolean functions that are used in this paper. Section III surveys properties of bent functions and partially-bent functions that are relevant to this work. This is followed by Section IV where the concept of plateaued functions is introduced. Important properties of plateaued functions are studies in Sections V and VI. Section VII investigates relationships between plateaued functions and partially-bent functions, while Section VIII shows methods for constructing plateaued functions that have useful cryptographic properties, such as balance, high algebraic degree, SAC and correlation immunity. Finally Section IX closes the paper with a pointer to some latest developments in the research into plateaued functions.

II. BOOLEAN FUNCTIONS

We consider functions from $V_n$ to $GF(2)$ (or simply functions on $V_n$), where $V_n$ is the vector space of $n$ tuples of elements from $GF(2)$. Usually we write a function $f$ on $V_n$ as $f(x)$, where $x = (x_1, \ldots, x_n)$ is the variable vector in $V_n$. The truth table of a function $f$ on $V_n$ is a $(0, 1)$-sequence defined by $(f(0_0), f(1_1), \ldots, f(1_{2^n-1}))$, and the sequence of $f$ is a $(1, -1)$-sequence defined by $((-1)^{f(0_0)}, (-1)^{f(1_1)}, \ldots, (-1)^{f(1_{2^n-1})})$, where $a_0 = (0, 0, \ldots, 0)$, $a_1 = (0, 0, 1, \ldots, 1)$, and $a_{2^n-1} = (1, \ldots, 1, 1)$. The matrix of $f$ is a $(1, -1)$-matrix of order $2^n$ defined by $M = ((-1)^{f(a_i \oplus a_j)})$ where $\oplus$ denotes the addition in $V_n$. $f$ is said to be balanced if its truth table contains an equal number of ones and zeros.

Given two sequences $\tilde{a} = (a_1, \ldots, a_m)$ and $\tilde{b} = (b_1, \ldots, b_m)$, their component-wise product is defined by $\tilde{a} \cdot \tilde{b} = (a_1 b_1, \ldots, a_m b_m)$ and the scalar product of $\tilde{a}$ and $\tilde{b}$, denoted by $(\tilde{a}, \tilde{b})$, is defined as the sum of the component-wise multiplications, where the operations are defined in the underlying field. In particular, if $m = 2^n$ and $\tilde{a}, \tilde{b}$ are the sequences of functions $f$ and $g$ on $V_n$ respectively, then $\tilde{a} \cdot \tilde{b}$ is the sequence of $f \oplus g$ where $\oplus$ denotes the addition in $GF(2)$.

An affine function $f$ on $V_n$ is a function that takes the form of $f(x_1, \ldots, x_n) = a_1 x_1 \oplus \cdots \oplus a_n x_n \oplus c$, where $\oplus$ denotes the addition in $GF(2)$ and $a_j, c \in GF(2)$. $j = $
1, 2, ..., n. Furthermore f is called a linear function if c = 0.

A (1, -1)-matrix A of order m is called a Hadamard matrix if AA^T = mI_m, where A^T is the transpose of A and I_m is the identity matrix of order m. A Sylvester-Hadamard matrix of order 2^n, denoted by H_n, is generated by the following recursive relation

\[ H_0 = 1, \quad H_n = \begin{bmatrix} H_{n-1} & H_{n-1} \\ H_{n-1} & -H_{n-1} \end{bmatrix}, \quad n = 1, 2, \ldots \]

Let \( \ell_i \), 0 \( i \leq n \), be the ith row of \( H_n \). Then \( \ell_i \) is the sequence of a linear function \( \varphi_i(x) \) defined by the scalar product \( \varphi_i(x) = \langle \alpha \cdot x \rangle \), where \( \alpha \in V_n \). Corresponds to the binary representation of an integer \( i, 0 = 0, 1, \ldots, 2^n - 1 \).

The Hamming weight of a (0, 1)-sequence \( \xi \), denoted by HW(\( \xi \)), is the number of ones in the sequence. Given two functions \( f \) and \( g \) on \( V_n \), the Hamming distance \( d(f, g) \) between them is defined as the Hamming weight of the truth table of \( f(x) \oplus g(x) \), where \( x = (x_1, \ldots, x_n) \).

**Definition 1:** The nonlinearity of a function \( f \) on \( V_n \), denoted by \( N_f \), is the minimal Hamming distance between \( f \) and all affine functions on \( V_n \), i.e., \( N_f = \min_{\alpha} d(f, \psi) \) where \( \psi_1, \psi_2, \ldots, \psi_{2^n+1} \) are all the affine functions on \( V_n \).

The following characterization of nonlinearity will be useful (for a proof see for instance [2]).

**Lemma 1:** The nonlinearity of \( f \) can be expressed by

\[
N_f = 2^{n-1} - \frac{1}{2} \max \{ \| \langle \xi, \ell_i \rangle \|, 0 \leq i \leq 2^n - 1 \}
\]

where \( \xi \) is the sequence of \( f \) and \( \ell_i \) is the ith row of \( H_n \), \( i = 0, 1, \ldots, 2^n - 1 \).

**Definition 2:** Let \( f \) be a function on \( V_n \). For a vector \( \alpha \in V_n \), denote by \( \xi(\alpha) \) the sequence of \( f(x \oplus \alpha) \). Thus \( \xi(0) \) is the sequence of itself and \( \xi(0) \oplus \xi(\alpha) \) is the sequence of \( f(x) \oplus f(x \oplus \alpha) \). Set \( \Delta(\alpha) = \langle \xi(0), \xi(\alpha) \rangle \), the scalar product of \( \xi(0) \) and \( \xi(\alpha) \). \( \Delta(\alpha) \) is also called the auto-correlation of \( f \) with a shift \( \alpha \).

**Definition 3:** Let \( f \) be a function on \( V_n \). We say that \( f \) satisfies the avalanche criterion with respect to \( \alpha \) if \( f(x) \oplus f(x \oplus \alpha) \) is a balanced function, where \( x = (x_1, \ldots, x_n) \) and \( \alpha \) is a vector in \( V_n \). Furthermore \( f \) is said to satisfy the avalanche criterion of degree \( k \) if it satisfies the avalanche criterion with respect to every non-zero vector \( \alpha \) whose Hamming weight is not larger than \( k \) (see [3]).

The strict avalanche criterion (SAC) [4] is the same as the avalanche criterion of degree one.

Obviously, \( \Delta(\alpha) = 0 \) if and only if \( f(x) \oplus f(x \oplus \alpha) \) is balanced, i.e., \( f \) satisfies the avalanche criterion with respect to \( \alpha \).

**Definition 4:** Let \( f \) be a function on \( V_n \). \( \alpha \in V_n \) is called a linear structure of \( f \) if \( \| \Delta(\alpha) \| = 2^n \).

For any function \( f \), \( \Delta(\alpha) = 2^n \), where \( \alpha_0 = 0 \), the zero vector on \( V_n \). Hence the zero vector is a linear structure of every function on \( V_n \). It is known that the set of all linear structures of a function \( f \) form a subspace of \( V_n \), whose dimension is called the linearity of \( f \). It is also well-known that if \( f \) has non-zero linear structures, then there exists a nonsingular \( n \times n \) matrix \( B \) over \( GF(2) \) such that \( f(x) = g(y) \oplus h(z) \), where \( x = (y, z) \), \( x \in V_n \), \( y \in V_p \), \( z \in V_q \), \( p + q = n \), \( g \) is a function on \( V_p \) that does not have non-zero linear structures, and \( h \) is a linear function on \( V_q \). Hence \( q \) is equal to the linearity of \( f \).

There exist a number of equivalent definitions of correlation-immune functions [5], [6]. The following definition is closely related to Definition 2.1 of [5].

**Definition 5:** Let \( f \) be a function on \( V_n \) and let \( \xi \) be its sequence. Then \( f \) is called a k-th-order correlation-immune function if \( \langle \xi, \ell \rangle = 0 \) for every \( \ell \), the sequence of a linear function \( \varphi(x) = \langle \alpha, x \rangle \) on \( V_n \), constrained by \( 1 \leq W(\alpha) \leq k \).

The following lemma is the re-statement of a relation proved in Section 2 of [1].

**Lemma 2:** For every function \( f \) on \( V_n \), we have

\[
\begin{aligned}
&\langle \Delta(\alpha_0), \Delta(\alpha_1), \ldots, \Delta(\alpha_{2^n-1}) \rangle H_n \\
= &\langle \langle \xi, \ell_0 \rangle^2, \langle \xi, \ell_1 \rangle^2, \ldots, \langle \xi, \ell_{2^n-1} \rangle^2 \rangle,
\end{aligned}
\]

where \( \ell_i \) is the ith row of \( H_n \), \( j = 0, 1, \ldots, 2^n - 1 \).

### III. Bent Functions and Partially-bent Functions

**Notation 1:** Let \( f \) be a function on \( V_n \), \( \xi \) the sequence of \( f \) and \( \ell_i \) denotes the ith row of \( H_n \), \( i = 0, 1, \ldots, 2^n - 1 \). Set \( \Sigma = \{ i \mid 0 \leq i \leq 2^n - 1, \langle \xi, \ell_i \rangle \neq 0 \}, \mathcal{R} = \{ \alpha \mid \Delta(\alpha) \neq 0, \alpha \in V_n \} \), and \( \Delta_M = \max\{\| \Delta(\alpha) \|, \alpha \in \Sigma - \{0\} \} \).

Note that to be more precise, \( 3, \mathcal{R} \) and \( \Delta_M \) should have been written as \( 3_f \), \( \mathcal{R_f} \) and \( \Delta_M(f) \) respectively. The subscript is omitted when no confusion occurs.

\( 3, \mathcal{R} \) and \( \Delta_M \) share an interesting property. Namely, \#\( 3, \#\mathcal{R} \) and \( \Delta_M \) are invariant under any nonsingular linear transformation on the variables, where \# denotes the cardinal number of a set.

Parseval’s equation states that \( \sum_{j=0}^{2^n-1} \langle \xi, \ell_j \rangle^2 = 2^{2n} \) (Page 416, [7]). Noticing \( \Delta(\alpha_0) = 2^n \), we can see that neither \( 3 \) nor \( \mathcal{R} \) is an empty set. \( 3 \) reflects the correlation immune property of \( f \), while \( \mathcal{R} \) reflects its avalanche characteristics and \( \Delta_M \) forecasts its avalanche property. Therefore information on \#\( 3 \), \#\( \mathcal{R} \) and \( \Delta_M \) is useful in investigating cryptographic characteristics of \( f \).

**Definition 6:** A function \( f \) on \( V_n \) is called a bent function [8] if \( \langle \xi, \ell_i \rangle^2 = 2^n \) for every \( i = 0, 1, \ldots, 2^n - 1 \), where \( \ell_i \) is the ith row of \( H_n \), \( i = 0, 1, \ldots, 2^n - 1 \).

A bent function on \( V_n \) exists only when \( n \) is even, and it achieves the maximum nonlinearity \( 2^{n-1} - 2^{\frac{n}{2}-1} \). From [8] and Parseval’s equation, we have the following:

**Theorem 1:** Let \( f \) be a function on \( V_n \) and \( \xi \) denote the sequence of \( f \). Then the following statements are equivalent:

(i) \( f \) is bent,
(ii) for each \( i, 0 \leq i \leq 2^n - 1, \langle \xi, \ell_i \rangle^2 = 2^n \) where \( \ell_i \) is the ith row of \( H_n \), \( i = 0, 1, \ldots, 2^n - 1 \),
(iii) \#\( \mathcal{R} \) = 1,
(iv) \( \Delta_M = 0 \),
(v) the nonlinearity of \( f \), \( N_f \), satisfies \( N_f = 2^{n-1} - 2^{\frac{n}{2}-1} \),
(vi) the matrix of \( f \) is an Hadamard matrix.
An interesting theorem of [1] explores a relationship between \#3 and \#R. This result can be expressed as follows.

**Theorem 2:** For any function \( f \) on \( V_n \), we have \((\#3)(\#R) \geq 2^n\), where the equality holds if and only if there exists a nonsingular \( n \times n \) matrix \( B \) over \( GF(2) \) and a vector \( \beta \in V_n \) such that \( f(xB \oplus \beta) = g(y \oplus h(z)) \), where \( x = (y, z), x \in V_n, y \in V_p, z \in V_q, p + q = n, g \) is a bent function on \( V_p \) and \( h \) is a linear function on \( V_q \).

Based on the above theorem, the concept of partially-bent functions was also introduced in the same paper [1].

**Definition 7:** A function on \( V_n \) is called a partially-bent function if \((\#3)(\#R) = 2^n\).

One can see that partially-bent functions include both bent functions and affine functions. Applying Theorem 2 together with properties of linear structures, or using Theorem 2 of [9] directly, we have

**Proposition 1:** A function \( f \) on \( V_n \) is a partially-bent function if and only if \(|\Delta(\alpha)|\) takes the value of \( 2^n \) or 0 only. Equivalently, \( f \) is a partially-bent function if and only if \( \mathbb{R} \) is composed of linear structures.

Some partially-bent functions are highly nonlinear and satisfy the SAC. Furthermore, some partially-bent functions are balanced. All these properties are useful in cryptography.

**IV. Plateaued Functions**

Now we introduce a new class of functions called plateaued functions. Here is the definition.

**Definition 8:** Let \( f \) be a function on \( V_n \) and \( \xi \) denote the sequence of \( f \). If there exists an even number \( r \), \( 0 \leq r \leq n \), such that \( \#\xi = 2^r \) and each \( (\xi, \ell_j)^2 \) takes the value of \( 2^{2^{n-r}} \) or 0 only, where \( \ell_j \) denotes the \( j \)th row of \( H_n \), \( j = 0, 1, \ldots, 2^n - 1 \), then \( f \) is called an \( r \)th-order plateaued function on \( V_n \). \( f \) is also simply called a plateaued function on \( V_n \) if we ignore the particular order \( r \).

Due to Parseval’s equation, the condition that \( \#\xi = 2^r \) can be obtained from the condition that “each \( (\xi, \ell_j)^2 \) takes the value of \( 2^{2^{n-r}} \) or 0 only, where \( \ell_j \) denotes the \( j \)th row of \( H_n \), \( j = 0, 1, \ldots, 2^n - 1 \).” For the sake of convenience, however, we have mentioned both conditions in Definition 8.

The following result can be obtained immediately from Definition 8.

**Proposition 2:** Let \( f \) be a function on \( V_n \). Then we have

(i) if \( f \) is an \( r \)th-order plateaued function then \( r \) must be even;

(ii) \( f \) is an \( n \)th-order plateaued function if and only if \( f \) is bent;

(iii) \( f \) is a \( 0 \)th-order plateaued function if and only if \( f \) is affine.

To help understand the definition of plateaued functions together with their relationships with affine and bent functions, profiles of \(|(\xi, \ell_j)|, j = 0, 1, \ldots, 2^n - 1\), of plateaued functions are depicted in Figure ???. The following is a consequence of Theorem 3 of [9].

**Proposition 3:** Every partially-bent function is a plateaued function.

An interesting question that arises naturally from Proposition 3 is whether a plateaued function is also partially-bent. In the coming sections we characterize plateaued functions and disprove the converse of the proposition.

**V. Characterizations of Plateaued Functions**

**Notation 2:** Let \( f \) be a function on \( V_n \) and \( \xi \) denote the sequence of \( f \). Let \( \chi \) denote the real valued \((0, 1)\)-sequence defined as \( \chi = (c_0, c_1, \ldots, c_{2^n - 1}) \) where \( c_j = \begin{cases} 1 & \text{if } j \in \Xi \text{ and } \alpha_j \in V_n \text{ is the binary representation of an integer } j \end{cases} \).

Write

\[
\chi H_n = (s_0, s_1, \ldots, s_{2^n - 1})
\]

where each \( s_j \) is an integer.

We note that

\[
\chi \left[ \begin{array}{c}
(\xi, \ell_0)^2 \\
(\xi, \ell_1)^2 \\
\vdots \\
(\xi, \ell_{2^n - 1})^2
\end{array} \right] = \sum_{j=0}^{2^n-1} (\xi, \ell_j)^2 = 2^{2n}
\]

where the second equality holds thanks to Parseval’s equation. By using Lemma 2, we have

\[
\chi H_n \left[ \begin{array}{c}
\Delta(\alpha_0) \\
\Delta(\alpha_1) \\
\vdots \\
\Delta(\alpha_{2^n-1})
\end{array} \right] = 2^{2n}
\]

Noticing \( \Delta(\alpha_0) = 2^n \), we obtain \( s_0 2^n + \sum_{j=1}^{2^n-1} s_j \Delta(\alpha_j) = 2^n \). Since

\[
\Delta(\alpha_j) = 0 \quad \text{if } \alpha_j \notin \mathbb{R}
\]

we have \( s_0 2^n + \sum_{\alpha_j \in \mathbb{R}, j > 0} s_j \Delta(\alpha_j) = 2^{2n} \). As \( s_0 = \#3 \), where \# denotes the cardinal number of a set, we have

\[
\sum_{\alpha_j \in \mathbb{R}, j > 0} s_j \Delta(\alpha_j) = 2^n (2^n - \#3) \quad \text{Note that}
\]

\[
2^n (2^n - \#3) = \sum_{\alpha_j \in \mathbb{R}, j > 0} s_j \Delta(\alpha_j)
\]

\[
\leq \sum_{\alpha_j \in \mathbb{R}, j > 0} |s_j \Delta(\alpha_j)|
\]

\[
\leq s_M \Delta_M (\# \mathbb{R} - 1)
\]

where \( s_M = \max\{|s_j|, 0 < j \leq 2^n - 1\} \). Hence the following inequality holds.

\[
s_M \Delta_M (\# \mathbb{R} - 1) \geq 2^n (2^n - \#3)
\]

From (1), we obtain

\[
\#3 \cdot 2^n = \sum_{j=0}^{2^n-1} s_j^2
\]

or \( \#3 (2^n - \#3) = \sum_{j=1}^{2^n-1} s_j^2 \)

Now we prove the first inequality that helps us understand properties of plateaued functions.
Theorem 3: Let $f$ be a function on $V_n$ and $\xi$ denote the sequence of $f$. Then
\[
\sum_{j=0}^{2^n-1} \Delta^2(\alpha_j) \geq \frac{2^{3n}}{\# \mathcal{A}}
\]
where the equality holds if and only if $f$ is a plateaued function.

Proof: By using (3), the property of Hölder’s Inequality [10], and (5), we obtain
\[
2^{2n} = \sum_{\alpha_j \in \mathcal{R}} s_j \Delta(\alpha_j) \leq \sum_{\alpha_j \in \mathcal{R}} |s_j \Delta(\alpha_j)|
\]
\[
\leq \left( \sum_{\alpha_j \in \mathcal{R}} s_j^2 \right) \left( \sum_{\alpha_j \in \mathcal{R}} \Delta^2(\alpha_j) \right)^{1/2}
\]
\[
\leq \left( \sum_{j=0}^{2^n-1} s_j^2 \right) \left( \sum_{j=0}^{2^n-1} \Delta^2(\alpha_j) \right)^{1/2}
\]
\[
= \sqrt{\# \mathcal{A} 2^n} \sum_{j=0}^{2^n-1} \Delta^2(\alpha_j) \quad (6)
\]
Hence $\frac{2^{2n}}{\# \mathcal{A}} \leq \sum_{j=0}^{2^n-1} \Delta^2(\alpha_j)$. We have proved the inequality in the theorem.

Assume that the equality in the theorem holds, i.e., $\sum_{j=0}^{2^n-1} \Delta^2(\alpha_j) = \frac{2^{2n}}{\# \mathcal{A}}$. This implies that all the equalities in (6) hold. Hence
\[
2^{2n} = \sum_{\alpha_j \in \mathcal{R}} s_j \Delta(\alpha_j) = \sum_{\alpha_j \in \mathcal{R}} |s_j \Delta(\alpha_j)|
\]
\[
= \left( \sum_{\alpha_j \in \mathcal{R}} s_j^2 \right) \left( \sum_{\alpha_j \in \mathcal{R}} \Delta^2(\alpha_j) \right)^{1/2}
\]
\[
= \left( \sum_{j=0}^{2^n-1} s_j^2 \right) \left( \sum_{j=0}^{2^n-1} \Delta^2(\alpha_j) \right)^{1/2}
\]
\[
= \sqrt{\# \mathcal{A} 2^n} \sum_{j=0}^{2^n-1} \Delta^2(\alpha_j) \quad (7)
\]
Applying the property of Hölder’s Inequality to (7), we conclude that
\[
|\Delta(\alpha_j)| = \nu |s_j|, \quad \alpha_j \in \mathcal{R}
\]
where $\nu > 0$ is a constant. Applying (8) and (5) to (7), we have
\[
2^{2n} = \sum_{\alpha_j \in \mathcal{R}} |s_j \Delta(\alpha_j)| = \sqrt{\# \mathcal{A} 2^n} \nu \sum_{j=0}^{2^n-1} s_j^2 = \nu \# \mathcal{A} 2^n \quad (9)
\]
From (7), we have $\sum_{\alpha_j \in \mathcal{R}} s_j \Delta(\alpha_j) = \sum_{\alpha_j \in \mathcal{R}} |s_j \Delta(\alpha_j)|$. Hence (8) can be expressed more accurately as follows
\[
\Delta(\alpha_j) = \nu s_j, \quad \alpha_j \in \mathcal{R}
\]
where $\nu > 0$ is a constant. From (7), it is easy to see that $\sum_{\alpha_j \in \mathcal{R}} s_j^2 = \sum_{j=0}^{2^n-1} s_j^2$. Hence
\[
s_j = 0 \quad \text{if} \quad \alpha_j \notin \mathcal{R} \quad (11)
\]
Combining (10), (11) and (2), we have
\[
\nu(s_0, s_1, \ldots, s_{2^n-1}) = (\Delta(\alpha_0), \Delta(\alpha_1), \ldots, \Delta(\alpha_{2^n-1}))
\]
Noting (1), we obtain
\[
\nu \chi H_n = (\Delta(\alpha_0), \Delta(\alpha_1), \ldots, \Delta(\alpha_{2^n-1}))
\]
Furthermore noting the equation in Lemma 2, we obtain
\[
2^n \nu \chi = (\langle \xi, \ell_0 \rangle^2, \ldots, \langle \xi, \ell_{2^n-1} \rangle^2)
\]
It should be pointed out that $\chi$ is a real valued (0,1)-sequence, containing $\# \mathcal{A}$ ones. By using Parseval’s equation, we obtain $2^n \nu(\# \mathcal{A}) = 2^{2n}$. Hence $\nu(\# \mathcal{A}) = 2^n$, and there exists an integer $r$ with $0 \leq r \leq n$ such that $\# \mathcal{A} = 2^r$ and $\nu = 2^{n-r}$. From (14) it is easy to see that $\langle \xi, \ell_j \rangle^2 = 2^{2n-r}$ or 0. Hence $r$ must be even. This proves that $f$ is a plateaued function.

Conversely assume that $f$ is a plateaued function. Then there exists an even number $r$, $0 \leq r \leq n$, such that $\# \mathcal{A} = 2^r$ and $\langle \xi, \ell_j \rangle^2 = 2^{2n-r}$ or 0. Considering Lemma 2, we have $\sum_{j=0}^{2^n-1} \Delta^2(\alpha_j) = 2^n \sum_{j=0}^{2^n-1} \langle \xi, \ell_j \rangle^4 = 2^{-n} \cdot 2^n \cdot 2^{4n-2r} = 2^{3n-r}$. Hence we have proved that $\sum_{\alpha_j \in \mathcal{R}} \Delta^2(\alpha_j) = \frac{2^{2n}}{\# \mathcal{A}}$.

Lemma 3: Let $f$ be a function on $V_n$ and $\xi$ denote the sequence of $f$. Then the nonlinearity $N_f$ of $f$ satisfies $N_f \leq 2^{n-1} - \frac{2^{n-1}}{\sqrt{\# \mathcal{A}}}$ where the equality holds if and only if $f$ is a plateaued function.

Proof: Set $p_M = \max\{|\langle \xi, \ell_j \rangle|, j = 0, 1, \ldots, 2^n - 1\}$, where $\ell_j$ is the $j$th row of $H_n$. Using Parseval’s equation, we obtain $p_M^2 \# \mathcal{A} \geq 2^{2n}$. Due to Lemma 1, we obtain $N_f \leq 2^{n-1} - \frac{2^{n-1}}{\sqrt{\# \mathcal{A}}}$. Assume that $f$ is a plateaued function. Then there exists an even number $r$, $0 \leq r \leq n$, such that $\# \mathcal{A} = 2^r$ and each $\langle \xi, \ell_j \rangle^2$ takes either the value of $2^{2n-r}$ or 0 only, where $\ell_j$ denotes the $j$th row of $H_n$, $j = 0, 1, \ldots, 2^n - 1$. Hence $p_M = 2^{n-r}$. Once again noting Lemma 1, we have $N_f = 2^{n-1} - 2^{n-1} - \frac{2^{n-1}}{\sqrt{\# \mathcal{A}}}$. Conversely assume that $N_f = 2^{n-1} - \frac{2^{n-1}}{\sqrt{\# \mathcal{A}}}$. From Lemma 1, we have also $N_f = 2^{n-1} - \frac{2^{n-1}}{\sqrt{\# \mathcal{A}}}$. Hence $p_M \sqrt{\# \mathcal{A}} = 2^{n-r}$. Since both $p_M$ and $\sqrt{\# \mathcal{A}}$ are integers and, more importantly, powers of two, we can let $\# \mathcal{A} = 2^r$, where $r$ is an integer with $0 \leq r \leq n$. Hence $p_M = 2^{n-r}$. Obviously $r$ is even. From Parseval’s equation, $\sum_{\ell_j \in \mathcal{A}} \langle \xi, \ell_j \rangle^2 = 2^{2n}$, together with the fact that $p_M^2 \# \mathcal{A} = 2^{2n}$, we conclude that $\langle \xi, \ell_j \rangle^2 = 2^{2n-r}$ for all $j \in \mathcal{A}$. This proves that $f$ is a plateaued function. ■

From the proof of Lemma 3, we can see that Lemma 3 can be stated in a different way as follows.
Lemma 4: Let $f$ be a function $f$ on $V_n$ and $\xi$ denote the sequence of $f$. Set $p_M = \max\{|(\xi, \xi_j)|, j = 0, 1, \ldots, 2^n - 1\}$, where $\xi_j$ is the $j$th row of $H_n$. Then $p_M \sqrt{\#3} \geq 2^n$ where the equality holds if and only if $f$ is a plateaued function.

Summarizing Theorem 3, Lemmas 3 and 4, we conclude

Theorem 4: Let $f$ be a function on $V_n$ and $\xi$ denote the sequence of $f$. Set $p_M = \max\{|(\xi, \xi_j)|, j = 0, 1, \ldots, 2^n - 1\}$, where $\xi_j$ is the $j$th row of $H_n$. Then the following statements are equivalent:

(i) $f$ is a plateaued function on $V_n$,

(ii) $\sum_{j=0}^{2^n-1} \Delta^2(\alpha_j) = \frac{2^n}{\#3}$,

(iii) the nonlinearity of $f$, $N_f$, satisfies $N_f = 2^{n-1} - \frac{2^n-1}{\sqrt{\#3}}$,

(iv) $p_M \sqrt{\#3} = 2^n$,

(v) $N_f = 2^{n-1} - 2^{-\frac{n-1}{2}} \sqrt{\sum_{j=0}^{2^n-1} \Delta^2(\alpha_j)}$.

Proof: Due to Theorem 3, Lemmas 3 and 4, (i), (ii), (iii) and (iv) hold. (v) follows from (ii) and (iii).

We now proceed to prove the second inequality that relates $\Delta(\alpha_j)$ to nonlinearity.

Theorem 5: Let $f$ be a function on $V_n$ and $\xi$ denote the sequence of $f$. Then the nonlinearity $N_f$ of $f$ satisfies

$$N_f \leq 2^{n-1} - 2^{-\frac{n-1}{2}} \sqrt{\sum_{j=0}^{2^n-1} \Delta^2(\alpha_j)}$$

where the equality holds if and only if $f$ is a plateaued function on $V_n$.

Proof: Set $p_M = \max\{|(\xi, \xi_j)|, j = 0, 1, \ldots, 2^n - 1\}$. Multiplying the equality in Lemma 2 by itself, we have

$$2^n \sum_{j=0}^{2^n-1} \Delta^2(\alpha_j) = \sum_{j=0}^{2^n-1} |\langle \xi, \xi_j \rangle|^4 \leq p_M^2 \sum_{j=0}^{2^n-1} |\langle \xi, \xi_j \rangle|^2.$$ 

Applying Parseval’s equation to the above equality, we have

$$\sum_{j=0}^{2^n-1} \Delta^2(\alpha_j) \leq 2^n p_M^{-1}.$$ 

Hence

$$p_M \geq 2^{-\frac{n-1}{2}} \sqrt{\sum_{j=0}^{2^n-1} \Delta^2(\alpha_j)}.$$ 

Thanks to Lemma 1, we have proved the inequality $N_f \leq 2^{n-1} - 2^{-\frac{n-1}{2}} \sqrt{\sum_{j=0}^{2^n-1} \Delta^2(\alpha_j)}$. The rest part of the theorem can be proved by using Theorem 4.

Theorem 3, Lemmas 3 and 4 and Theorem 4 represent characterizations of plateaued functions.

To close this section, let us note that since $\Delta(\alpha_j) = 2^n$ and $\#3 \leq 2^n$, we have $2^n - 2^{-\frac{n-1}{2}} \sqrt{\sum_{j=0}^{2^n-1} \Delta^2(\alpha_j)} \leq 2^{n-1} - 2^{-\frac{n-1}{2}}$ and $2^n - 2^{-\frac{n-1}{2}} \sqrt{\#3} \leq 2^{n-1} - 2^{-\frac{n-1}{2}}$. Hence both inequalities $N_f \leq 2^{n-1} - 2^{-\frac{n-1}{2}} \sqrt{\sum_{j=0}^{2^n-1} \Delta^2(\alpha_j)}$ and $N_f \leq 2^{n-1} - 2^{-\frac{n-1}{2}} \sqrt{\#3}$ are improvements on a more commonly used inequality $N_f \leq 2^{n-1} - 2^{-\frac{n-1}{2}}$.

VI. OTHER CRYPTOGRAPHIC PROPERTIES OF PLATEAUED FUNCTIONS

Lemma 1 implies that the following statement holds:

Proposition 4: Let $f$ be an $r$th-order plateaued function on $V_n$. Then the nonlinearity $N_f$ of $f$ satisfies $N_f = 2^{n-1} - 2^{-\frac{n-1}{2}}$.

The following result is the same as Theorem 18 of [11].

Lemma 5: Let $f$ be a function on $V_n$ $(n \geq 2)$, $\xi$ be the sequence of $f$, and $p$ be an integer, $2 \leq p \leq n$. If $\langle \xi, \xi_j \rangle = 0 \mod 2^{n-p+2}$, where $\xi_j$ is the $j$th row of $H_n$, $j = 0, 1, \ldots, 2^n - 1$, then the algebraic degree of $f$ is at most $p$.

Using Lemma 5, we obtain

Proposition 5: Let $f$ be an $r$th-order plateaued function on $V_n$. Then the algebraic degree of $f$, denoted by $\text{deg}(f)$, satisfies $\text{deg}(f) \leq \frac{r}{2} + 1$.

We note that the upper bound on algebraic degree in Proposition 5 is tight for $r < n$. For the case of $r = n$, the $n$th-order plateaued function is a bent function on $V_n$. [8] gives a better upper bound on the algebraic degree of a $n$th-order bent function on $V_n$. That bound is $\frac{r}{2}$.

The following property of plateaued functions can be verified by noting their definition.

Proposition 6: Let $f$ be an $r$th-order plateaued function on $V_n$, $B$ be any nonsingular $n \times n$ matrix over $GF(2)$ and $a$ be any vector in $V_n$. Then $f(xB \oplus a)$ is also an $r$th-order plateaued function on $V_n$.

Next we show that $r$th-order plateaued functions have the property that their linearity is bounded from above by $n-r$.

Theorem 6: Let $f$ be an $r$th-order plateaued function on $V_n$. Then the linearity of $f$, denoted by $q$, satisfies $q \leq n-r$, where the equality holds if and only if $f$ is partially-bent.

Proof: There exists a nonsingular $n \times n$ matrix $B$ over $GF(2)$ such that $f(xB) = (y \oplus h(z))$, where $x = (y, z)$, $y \in V_p$, $z \in V_q$, $p + q = n$, $g$ is a function on $V_p$ that does not have non-zero linear structures, and $h$ is a linear function on $V_q$. Hence $q$ is equal to the linearity of $f$. Set $f^*(x) = f(xB)$.

Let $\xi$, $\eta$ and $\zeta$ denote the sequences of $f^*$, $g$ and $h$ respectively. Then $\xi = \eta \times \zeta$, where $\times$ denotes the Kronecker product [12]. From the structure of $H_n$, we know that each row $L$ of $H_n$ can be expressed as $L = \ell \times e$, where $\ell$ is a row of $H_p$ and $e$ is a row of $H_q$. Then we have

$$\langle \xi, L \rangle = \langle \eta, \ell \rangle \langle \zeta, e \rangle = 2^q \langle \eta, \ell \rangle$$

(15)

Since $h$ is linear, $\zeta$ must be a row of $H_q$. Replacing $e$ by $\zeta$ in (15), we have

$$\langle \xi, L' \rangle = \langle \eta, \ell \rangle \langle \zeta, \zeta \rangle = 2^q \langle \eta, \ell \rangle$$

(16)

where $L' = \ell \times \zeta$ is still a row of $H_n$.

Note that $f^*$ is also an $r$th-order plateaued function on $V_n$. Hence $\langle \xi, L \rangle$ takes the value of $\pm 2^{n-r}$ or 0 only. Due to (16), $\langle \eta, \ell \rangle$ takes the value of $\pm 2^n - 2^{\frac{n-r}{2}}$ or 0 only. This proves that $g$ is an $r$th-order plateaued function on $V_q$. Hence $r \leq p$ and $r \leq n - q$, i.e., $q \leq n - r$.

Assume that $q = n - r$. Then $p = r$. From (16), each $\langle \eta, \ell \rangle$ takes the value of $\pm 2^n - 2^{\frac{n-r}{2}}$ or 0 only, where $\ell$ is any row of $H_p$. Hence applying Parseval’s equation to $g$, we can conclude that for each row $\ell$ of $H_p$, $\langle \eta, \ell \rangle$ cannot
take the value of zero. In other words, for each row \( \ell \) of \( H_p \), \(|\eta, \ell|\) takes the value of \( \pm 2^{\frac{p}{2}} \) only. Hence we have proved that \( g \) is a bent function on \( V_p \). Due to Theorem 2, \( f \) is partially-bent. Conversely, assume that \( f \) is partially-bent. Due to Theorem 2, \( g \) is a bent function on \( V_p \). Hence each \(|\eta, \ell|\) takes the value of \( \pm 2^{\frac{p}{2}} \) only, where \( \ell \) is any row of \( H_p \). As both \( \zeta \) and \( e \) are rows of \( H_p \), \(|\zeta, e|\) takes the value \( 2^n \) or 0 only. From (15), we conclude that \(|\xi, L|\) takes the value \( \pm 2^{n+\frac{p}{2}} \) or 0 only. Recall that \( f \) is an \( r \)th-order plateaued function on \( V_n \). Hence \( q + \frac{p}{2} = n - \frac{p}{2} \). This implies that \( r = p \), i.e., \( q = n - r \). ⊡

VII. RELATIONSHIPS BETWEEN PARTIALLY-BENT FUNCTIONS AND PLATEAUED FUNCTIONS

To examine more profound relationships between partially-bent functions and plateaued functions, we introduce a new characterization of partially-bent functions as follows.

**Theorem 7:** For every function \( f \) on \( V_n \), we have

\[
\frac{2^n - \#3}{\#3} \leq \frac{\Delta_M}{2^n} (\#R - 1)
\]

where the equality holds if and only if \( f \) is partially-bent.

**Proof:** From Notation 2, we have \( s_M \leq s_0 = \#3 \).

As a consequence of (4), we obtain the inequality in the theorem. Next we consider the equality in the theorem. Assume that the equality holds, i.e.,

\[
\Delta_M (\#R - 1) \#3 = 2^n (2^n - \#3)
\]  

(17)

From (3), we have

\[
2^n (2^n - \#3) \leq \sum_{\alpha_j \in \mathbb{R}, j > 0} |s_j| \Delta(\alpha_j)|
\]

\[
\leq \Delta_M \sum_{\alpha_j \in \mathbb{R}, j > 0} |s_j|
\]

\[
\leq \Delta_M (\#R - 1) \#3
\]  

(18)

From (17), we can see that all the equalities in (18) hold. Hence

\[
\Delta_M (\#R - 1) \#3 = \sum_{\alpha_j \in \mathbb{R}, j > 0} |s_j| \Delta(\alpha_j)|
\]  

(19)

Note that \(|s_j| \leq \#3\) and \(|\Delta(\alpha_j)| \leq \Delta_M\), for \( j > 0 \). Hence from (19), we obtain

\[
|s_j| = \#3 \quad \text{whenever } \alpha_j \in \mathbb{R} \text{ and } j > 0
\]

(20)

and \(|\Delta(\alpha_j)| = \Delta_M\) for all \( \alpha_j \in \mathbb{R} \) with \( j > 0 \).

Applying (20) to (5), and noticing that \( s_0 = \#3 \), we obtain \( \#3 = 2^n \), \( s_0^2 = \sum_{j=0}^{\#3} s_j^2 = (\#R)(\#3)^2 \). This results in \( 2^n \geq (\#R)(\#3) \). Together with the inequality in Theorem 2, it proves that \( (\#R)(\#3) = 2^n \), i.e., \( f \) is a partially-bent function.

Conversely assume that \( f \) is a partially-bent function, i.e., \((\#3)(\#R) = 2^n\). Then the inequality in the theorem is specialized as

\[
\Delta_M (2^n - \#3) \geq 2^n (2^n - \#3)
\]  

(21)

We need to examine two cases. Case 1: \( \#3 = 2^n \). Obviously the equality in (21) holds. Case 2: \( \#3 \neq 2^n \). From (21), we have \( \Delta_M \geq 2^n \). Thus \( \Delta_M = 2^n \). This completes the proof.

Next we consider a non-bent function \( f \). With such a function we have \( \Delta_M \neq 0 \). Thus from Theorem 7, we have the following result.

**Corollary 1:** For every non-bent function \( f \) on \( V_n \), we have

\[
\frac{(\#3)(\#R)}{\Delta_M} \geq \frac{2^n (2^n - \#3)}{\Delta_M} + \#3
\]

where the equality holds if and only if \( f \) is partially-bent (but not bent).

**Proposition 7:** For every non-bent function \( f \), we have

\[
\frac{2^n (2^n - \#3)}{\Delta_M} + \#3 \geq 2^n
\]

where the equality holds if and only if \( \#3 = 2^n \) or \( f \) has a non-zero linear structure.

**Proof:** Since \( \Delta_M \leq 2^n \), the inequality is obvious. On the other hand, it is easy to see that the equality holds if and only if \( (2^n - \Delta_M)(2^n - \#3) = 0 \).

From Proposition 7, one observes that for any non-bent function \( f \), Corollary 1 implies Theorem 2.

**Theorem 8:** Let \( f \) be an \( r \)th-order plateaued function. Then the following statements are equivalent:

(i) \( f \) is a partially-bent function,

(ii) \( \#R = 2^{n-r} \),

(iii) \( \Delta_M (\#R - 1) = 2^{n-r} - 2^n \),

(iv) the linearity \( q \) of \( f \) satisfies \( q = n - r \).

**Proof:** (i) \( \Rightarrow \) (ii). Since \( f \) is a partially-bent function, we have \((\#3)(\#R) = 2^n\). As \( f \) is also an \( r \)th-order plateaued function, \( \#3 = 2^n \) and hence \( \#R = 2^{n-r} \).

(ii) \( \Rightarrow \) (iii). When \( r = n \), we have \( \#R = 1 \) and hence (iii) holds. For the case of \( r < n \), using Theorem 7, we have \( \frac{2^n - \#3}{\Delta_M} \leq \frac{\Delta_M}{2^n} (\#R - 1) \) which is specialized as

\[
2^{n-r} - 1 \leq \frac{\Delta_M}{2^n} (2^{n-r} - 1)
\]

(22)

From (22) and the fact that \( \Delta_M \leq 2^n \), we obtain \( 2^{n-r} - 1 \leq \frac{\Delta_M}{2^n} (2^{n-r} - 1) \leq 2^{n-r} - 1 \). Hence \( \Delta_M = 2^n \). Since (ii) holds, we have \( \Delta_M (\#R - 1) = 2^{n-r} - 2^n \).

(iii) \( \Rightarrow \) (i). Note that (iii) implies \( 2^n - \#3 = \frac{\Delta_M}{2^n} (\#R - 1) \) where \( \#3 = 2^n \). By Theorem 7, \( f \) is partially-bent. Due to Theorem 6, we have (iv) \( \Leftrightarrow \) (i).

VIII. CONSTRUCTION OF PLATEAUED FUNCTIONS AND DISPROOF OF THE CONVERSE OF PROPOSITION 3

A. Existence of Balanced \( r \)th-order Plateaued Functions and Disproof of The Converse of Proposition 3

**Lemma 6:** For any integer \( k \) with \( k \geq 2 \), there exist \( k + 1 \) non-zero vectors in \( V_k \), say \( \gamma_0, \gamma_1, \ldots, \gamma_k \), such that for any non-zero vector \( \gamma \in V_k \), we have \((\gamma_0 \gamma), (\gamma_1 \gamma), \ldots, (\gamma_k \gamma) \neq (0, 0, \ldots, 0) \) and \((\gamma_0 \gamma), (\gamma_1 \gamma), \ldots, (\gamma_k \gamma) \neq (1, 1, \ldots, 1).

**Proof:** We choose \( k \) linearly independent vectors in \( V_k \), say \( \gamma_1, \ldots, \gamma_k \). From linear algebra, \((\gamma_1 \gamma), \ldots,
Let \( \alpha \) and \( \gamma \) go through all the non-zero vectors in \( V_k \) exactly once while \( \gamma \) goes through all the non-zero vectors in \( V_k \).

Hence there exists a unique \( \gamma^* \) satisfying

\[
((\gamma_1, \gamma^*), \ldots, (\gamma_k, \gamma^*)) = (1, \ldots, 1)
\]

As a consequence, for any non-zero vector \( \gamma \in V_k \) with \( \gamma \neq \gamma^* \), \( \{(\gamma_1, \gamma), \ldots, (\gamma_k, \gamma)\} \) contains both one and zero.

Let \( \gamma_0 \) be a non-zero vector in \( V_k \) such that \( \langle \gamma_0, \gamma^* \rangle = 0 \). Obviously \( \gamma_0 \notin \{(\gamma_1, \ldots, \gamma_k)\} \). It is easy to see that \( \gamma_0, \gamma_1, \ldots, \gamma_k \) satisfy the property in the lemma.

Let \( t \) and \( k \) be positive integers with \( k < 2t < 2^k \). Set \( n = t + k \) and \( r = 2n - 2k = 2t \). We now prove the existence of balanced \( r \)-order plateaued functions on \( V_n \) and disproves the converse of Proposition 3. In this section, we will not discuss \( r \)-th-order and \( 0 \)-th order plateaued function on \( V_n \) as they are simply bent and affine functions respectively.

Since \( t < k \), there exists a mapping \( P \) from \( V_t \) to \( V_k \) satisfying

(i) \( P(\beta) \neq P(\beta') \) if \( \beta \neq \beta' \),

(ii) \( \gamma_0, \gamma_1, \ldots, \gamma_k \in P(V_t) \), where \( P(V_t) = \{P(\beta)|\beta \in V_t\} \),

(iii) \( 0 \notin P(V_t) \) where \( 0 \) denotes the zero vector in \( V_k \).

We define a function \( f \) on \( V_{t+k} \) as follows

\[
f(x) = f(y, z) = P(y)z^T
\]

where \( x = (y, z) \), \( y \in V_t \) and \( z \in V_k \). Denote the sequence of \( f \) by \( \xi \).

Let \( L \) be a row of \( H_{t+k} \). Hence \( L = e \times \ell \) where \( e \) is a row of \( H_t \) and \( \ell \) is a row of \( H_k \). Once again from the properties of Sylvester-Hadamard matrices, \( L \) is the sequence of a linear function \( V_{t+k} \), denoted by \( \psi \), \( \psi(x) = \langle \alpha, x \rangle \), \( \alpha = (\beta, \gamma) \) and \( x = (y, z) \) where \( y, \beta \in V_t \) and \( z, \gamma \in V_k \). Hence \( \psi(x) = \langle \beta, y \rangle \oplus \langle \gamma, z \rangle \).

Note that

\[
(\xi, L) = \sum_{y \in V_t, z \in V_k} (-1)^{P(y)z^T \oplus (\langle \beta, y \rangle \oplus \langle \gamma, z \rangle)}
\]

\[
= \sum_{y \in V_t} (-1)^{\langle \beta, y \rangle} \sum_{z \in V_k} (-1)^{P(y)z^T}
\]

\[
= 2^k \sum_{y \in V_t} (-1)^{\langle \beta, y \rangle}
\]

\[
= \begin{cases} 
2^k(-1)^{\langle \beta, P^{-1}(\gamma) \rangle} & \text{if } P^{-1}(\gamma) \text{ exists} \\
0 & \text{otherwise}
\end{cases}
\]

Thus \( f \) is an \( r \)-th order plateaued function on \( V_n \).

Next we prove that \( f \) has no non-zero linear structures.

Let \( \alpha = (\beta, \gamma) \) be a non-zero vector in \( V_{t+k} \) where \( \beta \in V_t \) and \( \gamma \in V_k \),

\[
\Delta(\alpha) = \langle \xi, \xi(\alpha) \rangle
\]

\[
= \sum_{y \in V_t, z \in V_k} (-1)^{P(y)z^T \oplus P(y \oplus \beta)(z \oplus \gamma)z^T}
\]

\[
= \sum_{y \in V_t} (-1)^{P(y \oplus \beta)z^T} \sum_{z \in V_k} (-1)^{P(y)z^T} (y \oplus \beta)z^T
\]

There exist two cases to be considered: \( \beta \neq 0 \) and \( \beta = 0 \).

When \( \beta \neq 0 \), due to the property (i) of \( P \), we have \( P(y) \neq P(y \oplus \beta) \). Hence we have \( \sum_{y \in V_t} (-1)^{P(y)z^T} (y \oplus \beta)z^T = 0 \) from which it follows that \( \Delta(\alpha) = 0 \). On the other hand, when \( \beta = 0 \), we have \( \Delta(\alpha) = 2^k \sum_{y \in V_t} (-1)^{P(y)z^T} \).

Due to Lemma 6, \( P(y)z^T \) cannot be a constant. Hence \( \sum_{y \in V_t} (-1)^{P(y)z^T} = \pm 2^k \) which implies that \( \Delta(\alpha) \neq 2^k \).

Thus we can conclude that \( f \) has no non-zero linear structures.

Finally, due to the property (iii) of \( P \), \( f \) must be balanced. Therefore we have

Lemma 7: Let \( k, t \) be positive integers with \( k < 2t < 2^k \), \( n = t + k \) and \( r = 2t \). Then there exists a balanced \( r \)-order plateaued function on \( V_n \) that does not have a non-zero linear structure.

Lemma 7 not only indicates the existence of balanced plateaued function of any order \( r \) with \( 0 < r < n \), but also shows that the converse of Proposition 3 is not true.

\( f \) has some other interesting properties. In particular, due to Proposition 4, the nonlinearity \( N_f \) of \( f \) satisfies \( N_f = 2^{n-1} - 2^{n-2} - 1 \). Since \( f \) is not partially-bent, Theorem 2 tells us that \( \#(\beta, \beta) \geq 2^n \). This proves that \( \#(\beta, \beta) \geq 2^{n-2} \). On the other hand, from (25), we have \( \#(\beta, \beta) \leq 2^{n-2} - 2^{n-4} \). Thus we have \( 2^{n-2} - 2^{n-4} \leq \#(\beta, \beta) \leq 2^{n-2} \). It is important to note that such functions as \( f \) exist on \( V_n \) for both \( n \) even and odd.

Now we summarize the relationships among bent, partially-bent and plateaued functions. Let \( B_n \) denote the set of bent functions on \( V_n \), \( P_n \) denote the set of partially-bent functions on \( V_n \) and \( F_n \) denote the set of plateaued functions on \( V_n \), then the above results imply that \( B_n \subset P_n \subset F_n \), where \( C \) denotes the set of functions with \( \#(\beta, \beta) \geq 2^n \). Then the relationship among these classes of functions is shown in Figure ??.

Lemma 7 ensures that \( G_n \) is non-empty.

B. Constructing Balanced \( r \)-th order Plateaued Functions Satisfying SAC

Next we consider how to improve the function in the proof of Lemma 7 so as to obtain an \( r \)-th order plateaued function on \( V_n \) satisfying the strictly avalanche criterion (SAC), in addition to all the properties mentioned in Section VIII-A.

Note that if \( r \geq 2 \), i.e., \( t > 1 \), then from Section VIII-A, we have \( \#(\beta, \beta) \leq 2^{n-4} \). In other words, \( \#(\beta, \beta) > 2^{n-1} \), where \( \#(\beta, \beta) \) denotes the complementary set of \( \beta \). Hence there exist \( n \) linearly independent vectors in \( \mathbb{R}^c \). In other words, there exist \( n \) linearly independent vectors with respect to which \( f \) satisfies the avalanche criterion. Hence we can choose a nonsingular \( n \times n \) matrix \( A \) over \( \mathbb{F}_2 \) such that \( g(x) = f(xA) \) satisfies the SAC (see [13]). The nonsingular linear transformation \( A \) does not alter any of the properties of \( f \) discussed in Section VIII-A. Thus we have

Lemma 8: Let \( n \) be a positive number and \( r \) be any even number with \( 0 < r < n \). Then there exists a balanced
rth-order plateaued function on \( V_n \) that does not have a non-zero linear structure and satisfies the SAC.

C. Constructing Balanced rth-order Plateaued Functions Satisfying SAC and Having Maximum Algebraic Degree

We can further improve the function described in Section VIII-B so as to obtain an r-th order plateaued functions on \( V_n \) that have the highest algebraic degree and satisfy all the properties mentioned in Section VIII-B.

Theorem 1 in Chapter 13 of [7] allows us to verify that the following lemma is true.

Lemma 9: Let \( g \) be a function on \( V_n \). Then the degree of \( g \) is equal to \( n \) if and only if \( \# \{ \alpha \mid g(\alpha) = 1, \alpha \in V_n \} \) is odd.

As \( k > t \), it is easy to construct two mappings \( P' \) and \( P'' \) from \( V_t \) to \( V_k \) such that both satisfy properties (i), (ii) and (iii), mentioned in Section VIII-A, furthermore, \( P'(\alpha) = P''(\alpha) \) for \( \alpha \neq 0 \), and \( P'(0) \neq P''(0) \).

Note that \( P'(\alpha) = P''(\alpha) \) if \( \alpha \neq 0 \), and \( P'(0) \neq P''(0) \). Due to Lemma 9, it is easy to see that a component function of \( P' \otimes P'' \) has degree \( t \), and hence a component function of \( P' \) or \( P'' \) has degree \( t \). Without loss of generality, we assume that a component function of \( P' \) has degree \( t \), also \( P' \) is identified with \( P \), which we used in Sections VIII-A and VIII-B. Hence the function \( f \) has degree \( t + 1 \).

We have now constructed an rth-order plateaued function with algebraic degree \( \frac{r}{2} + 1 \). Applying the discussions in Sections VIII-A and VIII-B, we can obtain an r-th order plateaued function on \( V_n \) having algebraic degree \( \frac{r}{2} + 1 \) and satisfying all the properties of the function constructed in Section VIII-A and VIII-B. It should be noted that the function constructed in this subsection achieves the highest possible algebraic degree given in Proposition 5. Thus the upper bound on the algebraic degree of plateaued functions, mentioned in Proposition 5, is tight. Hence we have the following result.

Theorem 9: Let \( k, t \) be positive integers with \( k < 2^t < 2^k \), \( n = t + k \) and \( r = 2t \). Then there exists a balanced r-th order plateaued function on \( V_n \) that does not have a non-zero linear structure, satisfies the SAC and has the highest possible algebraic degree \( \frac{r}{2} + 1 \).

D. Constructing Balanced r-th Order Plateaued and Correlation Immune Functions

Let \( f \) be a function on \( V_n \), \( \xi \) be the sequence of \( f \) and \( t_i \) denote the ith row of \( H_n \), \( i = 0, 1, \ldots, 2^n - 1 \). Recall that in Notation 1, we defined \( \mathcal{H}_f = \{ i \mid 0 \leq i \leq 2^n - 1, (\xi, \ell_i) \neq 0 \} \). Now let \( \mathcal{N}_f = \{ \alpha_i \mid 0 \leq i \leq 2^n - 1, i \in \mathcal{H}_f \} \). \( \mathcal{N}_f \) will be used in the following description of constructing plateaued functions that are correlation immune.

Lemma 10: Let \( f \) be a function on \( V_n \), \( \xi \) be the sequence of \( f \), and \( t_i \) denote the ith row of \( H_n \). Also let \( W \) be an \( r \)-dimensional linear subspace of \( V_n \) such that \( \mathcal{N}_f \subseteq W \), and \( s = \frac{r}{2^t} \) where \( \frac{r}{2^t} \) denotes the maximum integer not larger than \( \frac{r}{2^t} \). Then there exists a nonsingular \( n \times n \) matrix \( B \) on \( GF(2) \) such that \( h(y) = f(yB) \) is an \((s - 1)\)-th order correlation immune function.

Proof: For the sake of convenience, let \( 0_t \) denote the all-zero sequence of length \( t \) and \( 1_t \) denote the all-one sequence of length \( i \). Define \( \sigma_j \in \mathcal{V}_n, j = 1, \ldots, r \), as follows:

\[
\begin{align*}
\sigma_1 & = (1, 0, \ldots, 0, 0_{n - (r - 1)})_s, \\
\sigma_2 & = (0, 1, 0, \ldots, 0, 0_{n - (r - 1)})_s, \\
& \ldots \\
\sigma_{r - 1} & = (0, \ldots, 0, 1, 0_{n - (r - 1)})_s, \\
\sigma_r & = (0, \ldots, 0, 1_{n - (r - 1)})_s.
\end{align*}
\]

Since \( n \geq rs \), the length of \( 0_{n - (r - 1)} \) is at least \( s \). Note that the linear combinations of \( \sigma_1, \ldots, \sigma_r \) form an \( r \)-dimensional linear subspace \( U \) of \( V_n \), and each non-zero vector in \( U \) has a Hamming weight of at least \( s \). Since both \( W \) and \( U \) are \( r \)-dimensional, there exists a nonsingular \( n \times n \) matrix \( B \) on \( GF(2) \) satisfying \( UB = W \), where \( UB = \{ \gamma B \mid \gamma \in \mathcal{U} \} \). Define a function \( h \) on \( V_n \) such that \( h(y) = f(yB) \). Since \( \mathcal{N}_f \subseteq W \), we have \( \mathcal{N}_f \subseteq U \). Let \( \alpha \) be a non-zero vector in \( V_n \) whose Hamming weight is at most \( s - 1 \). Obviously \( \alpha \notin U \) and hence \( \alpha \notin \mathcal{N}_f \). Therefore for any sequence \( \ell \) of a linear function \( \varphi(x) = (\alpha, x) \) on \( V_n \), constrained by \( 1 \leq W(\alpha) = s - 1 \), we have \( (\eta, \ell) = 0 \), where \( \eta \) denotes the sequence of \( h \). This proves that \( h(y) = f(yB) \) is an \((s - 1)\)-th order correlation immune function.

By using the method described in Section VIII-A, we can construct plateaued functions that are correlation immune, highly nonlinear and do not have non-zero linear structures. More specifically, since \( k \geq t + 1 \), there exists a \((t + 1)\)-dimensional subspace of \( V_n \). Denote the subspace by \( W \). In the proof of Lemma 6, we can impose on the mapping \( P \) a condition that \( P(V_i) \subseteq W \). From (24), we have \( \alpha = (\beta, \gamma) \in \mathcal{N}_f \) if and only if \( P^{-1}(\gamma) \) exists, where \( \beta \in V_t \) and \( \gamma \in V_k \). In other words, \( \mathcal{N}_f = (V_t, P(V_i)) \) where \( (V_t, P(V_i)) = \{ (\beta, \gamma) \mid \beta \in V_t, \gamma \in P(V_i) \} \). Hence \( \mathcal{N}_f \subset (V_t, W) \). Note that \( (V_t, W) \) is a \((2t + 1)\)-dimensional subspace of \( V_{t+k} \). From Lemma 10, we know that there exists a nonsingular \( n \times n \) matrix \( B \) on \( GF(2) \) such that \( h(y) = f(yB) \) is an \((s - 1)\)-th order correlation immune function, where \( s = \left\lfloor \frac{n}{t+1} \right\rfloor \) or \( s = \left\lceil \frac{n}{t+1} \right\rceil \). The function \( h \) satisfies all the other useful properties mentioned in Section VIII-A. That is, in addition to being correlation immune, \( h \) is balanced, highly nonlinear, and does not have non-zero linear structures. Furthermore \( h \) satisfies \( 2^{n-r} < \# \mathcal{N}_h \leq 2^{n-\frac{r}{2}} \). Hence we have proved.

Theorem 10: Let \( k \) and \( t \) be positive integers with \( k < 2^t < 2^k \). Let \( n = k + t \) and \( r = 2t \). Then there exists an \( r \)-th order plateaued function on \( V_n \) that is also an \((s - 1)\)-th order correlation immune function, where \( s = \left\lceil \frac{n}{t+1} \right\rceil \) or \( s = \left\lceil \frac{n}{t+1} \right\rceil \), and does not have a non-zero linear structure.

IX. Conclusions

We have introduced and characterized a new class of functions called plateaued functions. These functions bring together various nonlinear characteristics. We have also shown that partially-bent functions are a proper subset of
plateaued functions. We have further demonstrated methods for constructing plateaued functions that have many cryptographically desirable properties including balance, SAC, high algebraic degree, high nonlinearity and correlation immunity.

Building on the results obtained in this work, more recently we have introduced complementary plateaued functions. These functions have made it possible for us to discover new methods for constructing bent functions, as well as highly nonlinear balanced functions. Details on these new developments can be found in [14]. Finally, we note that a close relationship between plateaued functions and highly nonlinear correlation immune functions has recently been identified in [15].
